KEYWORDS

Animal-assisted therapy; Systematic review; Randomized controlled trials **Summary** The objectives of this review were to summarize the evidence from randomized controlled trials (RCTs) on the effects of animal-assisted therapy (AAT). Studies were eligible if they were RCTs. Studies included one treatment group in which AAT was applied. We searched the following databases from 1990 up to October 31, 2012: MEDLINE via PubMed, CINAHL, Web of Science, Ichushi Web, GHL, WPRIM, and PsycINFO. We also searched all Cochrane Database up to October 31, 2012. Eleven RCTs were identified, and seven studies were about ''Mental and behavioral disorders''. Types of animal intervention were dog, cat, dolphin, bird, cow, rabbit, ferret, and guinea pig. The RCTs conducted have been of relatively low quality. We could not perform meta-analysis because of heterogeneity.

In a study environment limited to the people who like animals, AAT may be an effective treatment for mental and behavioral disorders such as depression, schizophrenia, and alcohol/drug addictions, and is based on a holistic approach through interaction with animals in nature.

Introduction

Animals have been our companions since ancient times, and we are well aware of the many ways that some of them have aided us throughout history.¹ Animals are used to help humans in ways; for example, serving as working shire horses and guide dogs for the blind.² The modalities that use animals as tools for improving physical, mental and social functions, and educational and welfare aspects of humans are called animal-assisted interventions (AAI).

To understand the different types of AAI and integrate some useful definitions, we accepted the classification of the American Veterinary Medical Association (AVMA).³ The AVMA classifies AAI into three category: (i) animal-assisted

Effectiveness of animal-assisted therapy

activities (AAA) that utilize companion animals, (ii) animal assisted-therapy (AAT) that utilizes therapy animals, and (iii) service animal programs (SAP) that utilize service animal. Especially, AAT is a goal-directed intervention in which an animal that meets specific criteria is an integral part of the treatment process. These programs are usually directed and delivered by human health or human services professionals with specialized expertise and within the scope of practice of their profession.

A pioneer systematic review (SR) of AAT showed that overall it was associated with moderate effects in improving outcomes in four areas: autism-spectrum symptoms, medical difficulties, behavioral problems, and emotional well-being.⁴ However, contrary to expectations, characteristics of the SR participants and studies did not produce differential outcomes. Some limitations of the SR were that it only included articles published prior to 2004, and it did not include randomized controlled trials (RCTs).

It is well known in research design that evidence grading is highest for a SR with meta-analysis of RCTs. Although many studies have reported the effects of AAT,^{1,4,5} there is no SR of the evidence based on RCTs. Therefore, the objective of this review was to summarize the evidence from RCTs on the effects of AAT.

Methods

Criteria for considering studies included in this review

Types of studies Studies were eligible if they were RCTs.

Types of participants

There was no restriction on participants.

Types of intervention and language

Studies included at least one treatment group in which AAT was applied. The definition of AAT in this study was based on the classification of the AVMA.³ Type of animal was not a restriction but we excluded robotic animals (e.g., robotic dog). There was no restriction on the basis of language.

Types of outcome measures

We focused on all cure and rehabilitation effects using the International Classification of Diseases-10 (ICD-10).

Search methods for identification of studies

Bibliographic database

We searched the following databases from 1990 up to October 31, 2012: MEDLINE via PubMed, CINAHL, Web of Science, Ichushi Web (in Japanese), the Global Health Library (GHL), the Western Pacific Region Index Medicus (WPRIM), and PsycINFO. We also searched the Cochrane Database of Systematic Reviews (Cochrane Reviews), the Database of Abstracts of Reviews of Effects (DARE), the Cochrane Central Register of Controlled Trials (CENTRAL), the Cochrane Methodology Register (Methods Studies), the Health Technology Assessment Database (Technology Assessments), the NHS Economic Evaluation Database (NHS EED), The Cochrane Collaboration databases (Cochrane Groups), and the Campbell Systematic Reviews (the Campbell Collaboration) up to October 31, 2012. All searches were performed by a specific searcher (hospital librarian) who was qualified in medical information handling, and who was sophisticated in searches of clinical trials.

Search strategies

The special search strategies contained the elements and terms for MEDLINE, CINAHL, Web of Science, Ichushi Web, GHL, WPRIM, PsycINFO, and All Cochrane databases (Table 1). Only keywords relating to the intervention were used for the searches. Titles and abstracts of identified published articles were reviewed in order to determine the relevance of the articles. References in relevant studies and identified RCTs were screened.

Registry checking

We searched the International Clinical Trials Registry Platform (ICTRP), the International Prospective Register of Systematic Review (PROSPERO), the Clinical Trials.gov registry, and the University Hospital Medical Information Network-Clinical Trials Registry (UMIN-CTR) up to October 31, 2012. ICTRP in the WHO Registry Network meets specific criteria for content, quality and validity, accessibility, unique identification, technical capacity and administration. Primary registries meet the requirements of the ICMJE. Clinical Trials.gov is a registry of federally and privately supported clinical trials conducted in the United States (US) and around the world. UMIN-CTR registers clinical trials conducted in Japan and around the world.

Handsearching, reference checking, and other

We handsearched abstracts published in AAT and relevant journals in Japan. We checked the references of included studies for further relevant literature.

Review methods

Selection of trials

In order to make the final selection of studies for the review, all criteria were applied independently by four authors (e.g., TH, JK, SP, and SO) to the full text of articles that had passed the first eligibility screening (Fig. 1). Disagreements and uncertainties were resolved by discussion with other author (e.g., HK, KT, and YM).

Studies were selected when (i) the design was a RCT and (ii) one of the interventions was a form of AAT. Protocols without results were excluded, and we included only completed studies. Cure and rehabilitation effects were used as a primary outcome measure. Trials that were excluded were presented with reasons for exclusion (Appendix).

Risk of bias (quality) assessment

In order to ensure that variation was not caused by systematic errors in the study design or execution, three review authors (HO, SP, and TH) independently assessed the quality of articles. A full quality appraisal of these papers was made using the Cochrane's criteria list for the methodological quality assessment.⁶ Disagreements and uncertainties

Δ

Table 1The special search strategies.

限定 - 出版日 (開始): 19900101-; 人間; 言語: English, Japanese; 出版物タイプ: Clinical Trial, Journal Article, Randomized Controlled Trial 検索モード - 入力した語順どおりに検索

were resolved by discussion with other authors (e.g., HO, SO, and HK).

Each item was scored as 'yes' (y), 'no' (n), 'do not know or unclear' (?), or 'not applicable' (n/a). Depending on the study design, some items were not applicable. The ''n/a'' was excluded from calculation for quality assessment. We displayed the percentage of present description on all 11check items for the quality assessment of articles. Then, based on the percentage of risk of poor methodology and/or bias, each item was assigned to the following categories: good description (80–100%), poor description (50–79%), or very poor description (0–49%). Inter-rater reliability was calculated on a dichotomous scale using percentage agreement and Cohen's kappa coefficient (k).

Summary of studies and data extraction

Ten review authors (HP, HO, SH, TO, SP, TA, TH, JK, SO and HK) described the summary from each article based on the recommended structured abstracts.^{7,8}

Benefit, harm, and cost

The GRADE Working Group⁹ reported that the balance between benefit and harm, quality of evidence, applicability, and certainty of the baseline risk were all considered in judgments about the strength of recommendations. Adverse events (harm) and cost for intervention were especially important information for researchers and users of clinical practice guidelines, and we presented this information with the description of each article.

Analysis

Pre-planned stratified analyses were: (a) trials comparing AAT with no treatment or waiting list controls, (b) trials comparing different types of general rehabilitation methods (e.g., physical therapy, occupational therapy), and (c) trials comparing AAT with other different intervention(s). We expressed the results of each RCT, when possible, as relative risk (RR) with corresponding 95 percent confidence intervals (95%CI) for dichotomous data, and as standardized or weighted mean differences (SMD) with 95%CI for

Figure 1 Flowchart of trial process.

Effectiveness of animal-assisted therapy

continuous data. Heterogeneous results of studies that provided by inclusion criteria were not combined.

Research protocol registration

We submitted and registered our research protocol to the PROSPERO database (no. CRD42012003032),¹⁰ an international database of prospectively registered SRs in health and social care. Key features from the review protocol are recorded and maintained as a permanent record in PROSPERO. This provides a comprehensive listing of SRs registered at inception, and enables comparison of reported review findings with what was planned in the protocol. PROS-PERO is managed by CRD and funded by the UK National Institute for Health Research (NIHR). Registration was recommended because it encourages full publication of the review's findings.¹¹

Results

Study selection

The literature searches based on databases included potentially relevant articles (Fig. 1). Abstracts from those articles were assessed, and 57 papers were retrieved for further evaluation (checks for relevant literature). Forty-six publications were excluded because they did not meet the eligibility criteria (see Appendix). Eleven studies^{12–22} met all inclusion criteria (Table 1).

Study characteristics

The language of all eligible publications was English. Target diseases and/or symptoms (Table 2) were schizophrenia,^{12,19,20} cancer,¹³ advanced heart failure,¹⁴ depression,^{15,21} ambulatory motor impairment,¹⁶ older adults admitted to skilled rehabilitation units,¹⁷ elderly persons with chronic psychiatric, medical, and neurologic conditions,¹⁸ and a mental illness diagnosis as well as a history of alcohol/drug abuse or other addictive behaviors.²²

Based on ICD-10, we identified a disease targeted in each article (Table 3). Among 11 studies, seven studies were about "Mental and behavioral disorders (F10-19,²² F20,^{12,19,20} F30-33,^{15,21} and the unidentified due to including many geriatric disease¹⁸)". There was one study each in "Neoplasms (C00-D48; the unidentified due to many site of cancer)",¹³ "Diseases of the circulatory system (I50.1)",¹⁴ and "Injury, positioning and certain other consequences of external causes (T90-93)".¹⁶ Because there were a variety of target disease.¹⁷

Types of animal studied included dog,^{12-14,16,18,19} dog or cat, ²⁰ dolphin,¹⁵ bird,¹⁷ cow,²¹ and dog, rabbit, ferret, and guinea pig.²²

In a study for inpatients with schizophrenia,¹² compared with the control group, the dog treatment group showed significant improvement on all measures expect for social support and negative psychiatric symptoms. The results of the study showed that AAT can promote significant improvements in many clinical aspects among inpatients with schizophrenia. Similarly, in a study for inpatients with schizophrenia,¹⁹ the dog intervention group showed significant improvements in the living skill profile, social contact score, and in the positive and negative symptom dimensions. On the other hand, the control group also showed significant positive changes in positive and general symptoms. No differences were found between the two groups before and after the application of the intervention. As for elderly schizophrenic patients, a controlled 1-year study provided subjects with their own dog or cat as the intervention animal, according to personal preference.²⁰ The Social Adaptive Functioning Evaluation (SAFE) scores at termination of the study showed significant improvement compared with baseline scores, and were significantly more positive for the AAT group on both Total SAFE score and on the Social Functions subscale.

A study tried to identify to what extent an AAT (i.e., visits with a dog) affects mood, self-perceived health, and sense of coherence among patients undergoing radiation therapy for cancer.¹³ Results showed no statistically significant differences within or between groups in mood, sense of coherence, or two facets of self-perceived health.

An AAT was performed in patients hospitalized with heart failure.¹⁴ The study tried to determine whether a 12-min hospital visit with a therapy dog improves hemodynamic measures, lowers neurohormone levels, and decreases state anxiety in patients with advanced heart failure. Compared with controls, the volunteer-dog group had significantly greater decreases in systolic pulmonary artery pressure and pulmonary capillary wedge pressure during and after the intervention.

A study based on dolphins was performed to evaluate the effectiveness of animal facilitated therapy with dolphins, controlling for the influence of the natural setting, in the treatment of mild to moderate depression.¹⁵ For the participants who completed the study, the mean severity of the depressive symptoms was more reduced in the treatment group than in the control group.

A study reported the effectiveness of dog intervention for people with severe ambulatory disability.¹⁶ Significant positive changes in all but two dependent measures were associated with the presence of a service dog both between and within groups. Psychologically, all participants showed substantial improvements in self-esteem, internal locus of control, and psychological well-being within six months after receiving their dog. Socially, all participants showed similar improvements in community integration. Demographically, all participants showed increases in school attendance and/or part-time employment. Economically, all participants showed dramatic decreases in the number of both paid and unpaid assistance hours.

An avian interventional study was performed to examine the alleviation effect on depression, loneliness, and morale of older adults in skilled rehabilitation units.¹⁷ In the presence of a companion bird, the experimental group showed a significant decrease in depression, but no decrease in morale or loneliness was observed in the control group that was without a bird.

A dog interventional study was performed to evaluate the effects on geriatric psychiatry inpatients.¹⁸ No significant differences in the Multidimensional Observation Scale for Elderly Subjects scores were found between or within

Oncology Nursing Forum 2008;35:225–232. Animal-assisted activity among patients with cancer: effects on mood, fatigue, self-perceived health, and sense of coherence	Cole KM. et al. Am J Crit Care 2007;16:575–585 Animal-assisted therapy in patients hospitalized with heart failure
Aim/objective	To evaluate the effects of animal-assisted activity on self-esteem, control over activities of daily living, and other psycho-physiological aspects among Taiwanese inpatients with schizophrenia	To identify to what extent an animal-assisted activity (i.e., visits with a dog) affects the mood, self-perceived health, and sense of coherence among patients undergoing radiation therapy.	To determine whether a 12-min hospital visit with a therapy dog improves hemodynamic measures, lowers neurohormone levels, and decreases state anxiety in patients with advanced heart failure
Setting/place	Psychiatric institution in Hualien Country, located in eastern Taiwan	Outpatient radiation therapy units of two hospitals in a mid-sized, midwestern city, USA	The cardiac care unit or the cardiac observation unit
Participants	30 adult patients with schizophrenia	30 adult patients undergoing nonpalliative radiation therapy	76 adult patients with a diagnosis of advanced heart failure
Intervention	Weekly 50-min animal-assisted activity sessions were arranged for the patients of the treatment group over a period of 2 months. Patients in the control group received treatment as usual. The animal-assisted activity was held in the hospital's garden but took place in the activity hall during inclement weather and during the first 2 weeks of the study so as not to distract the patients. The animals used in this study were two healthy, friendly, medium-sized, trained dogs of nonspecific breeds. They were provided by trainers, but during interactions with patients were accompanied only by the investigators	Patients participated in 15-min sessions three times per week for four weeks. Dog visit group: Two visitor dogs used in the study were certified by the College of Veterinary Medicine at the University of Missouri Pet-assisted Love and support (PAL5) program. Dogs were selected for quiet temperaments, friendliness with strangers, and length of visitation experience. During the sessions, participants combed, petted, played, and talked with the dog. The dog handlers introduced the dog to the participant during first session and were instructed to avoid conversation with the participants. Friendly human visit group: Participants met individually with the same adult. Friendly human visitors were volunteer nursing students, emeritus nursing faculty, hospital administrative staff from other departments, and community members. Reading group: Participants read silently researcher-provided magazines. Magazines were selected based on lack of content related to health and fitness, cancer and treatments, selfhelp, counseling, pets, AAA, and animal-assisted therapy	Patients randomly assigned to the experimental group received a visit from a volunteer and a dog. The type of dog breed was not controlled for; 14 dogs of 10 various breeds were used. The 14 dogs included 1 extra-large dog, 6 large dogs, 5 medium dogs, and 2 small dogs. Each visit was conducted according to the guidelines taught during the volunteer and dog orientation: (1) volunteer introduces self and dog, (2) patient washes his or her hands before the visit, (3) dog lies on the bed with its head within 0.6 m (2 ft) of the patient's head on a clean sheet used as a barrier to the patient's bed, (4) patients may pet the dog and talk to the dog and volunteer and (5) patient washes his or her hands after the visit. No attempt was made to control the content of the conversation during the visit. The visit lasted for 12 min. After the visit, an instant self-developing photograph was taken of the patient with the dog and given to the patient. Patients randomly assigned to the volunteer-only group received a 12-min visit from a volunteer. The volunteer introduced himself or herself, sat in a chair approximately 1.2 m (4ft) from the patient's head, and let the patient know that the visit would last for 12 min if the patient was up to it. No attempt was made to control for the volunteer's usual conversation during the visit. No patient requested to end any earlier than 12 min. Patients randomly assigned to the control group were asked to lie quietly without talking unless they had a specific need or request. For all groups, a sign was placed on the patient's do or or curtain asking everyone to please not interrupt during the 12-min interaction and data collection, unless an emergency occurred. Volunteers participating in the volunteer-dog teams were used for the volunteer-only group as much as possible to minimize any influence of a volunteer's personality on the results. For all groups, data were collected at baseline immediately before the visit, 8 min after the intervention started, and at 16 min, which was 4 min af
Main and secondary outcomes	Self-esteem, self-determination, extent of social support and increases and decreases in adverse psychiatric symptoms	Mood:Profile of Mood States (POMS), Self-perceived health:Self-perceived health questionnaire, Sense of coherence:Orientation to Life Questionnaire(OTLQ), Exit questionnaire: Participants completed this five-item tool that was developed by the research team	Heart rate, cardiac index, plasma levels of catecholamines, and anxiety
Randomization Blinding/masking	No description No description	Via a computer-generated random-numbering system No description	Using a table of random numbers Data collectors did not speak to the patients during the measurement of outcome variables and the intervention
Numbers randomized	Treatment group ($n = 15$) and control group ($n = 15$)	The dog visit group (treatment group) (<i>n</i> = 10), friendly human visit group (<i>n</i> = 10), or quiet reading group (<i>n</i> = 10)	Volunteer-dog team group (n = 26), volunteer only group (n = 25), and control group (n = 25)
Recruitment	The participants in this study were patients selected from a 600-bed psychiatric institution in Hualien County, located in eastern Taiwan	28 Caucasian and 2 African American adults with no known pet allergies who were beginning nonpalliative (first-line) radiation therapy for cancer for a period of at least four weeks following initial diagnosis	76 adults patients with a diagnosis of advanced heart failure admitted to the cardiac care unit or the cardiac observation unit
Numbers analyzed	Treatment group $(n = 12)$ and control group $(n = 15)$	The dog visit group (treatment group) ($n = 10$), friendly human visit group ($n = 10$), or quiet reading group ($n = 10$)	Volunteer-dog team group ($n=26$), volunteer only group ($n=25$), and control group ($n=25$)

groups before and after the interventions. There was a non-significant tendency for subjects who received the dog intervention to have less irritable behavior after treatment. However, women with dementia who received either pet therapy or exercise intervention had improved irritable behavior scores after treatment.

A unique study was performed to examine potential changes in mental health in people with clinical depression who were working with farm animals as the only task on a farm.²¹ The intervention consisted of work and interaction with farm animals twice a week for 12 weeks. Those who participated in animal-assisted therapy experienced statistically significant changes in depression and generalized self-efficacy. Additionally, more participants in the intervention could have been beneficial for the subgroups of clients and served as a useful supplement within mental health care, although these changes were not significantly different from those in the control group.

A study evaluated whether patients such as those with a mental illness diagnosis as well as a history of alcohol/drug abuse or other addictive behaviors in the AAT group would show a greater increase in observed appropriate social behaviors than patients in the control group.²² AAT patients interacted more with other patients. Similarly, there was a main effect that lasted for weeks, with improvement in scores over time but no interaction between weeks and groups. There was a similar finding for the AAT group; patients smiled and showed pleasure significantly more often than the control group and thus improved over four weeks, with no interaction between weeks and groups.

Quality assessment

We evaluated 11 items from the Cochrane's criteria list in more detail (Table 4). Inter-rater reliability metrics for the quality assessment indicated substantial agreement for all 121 items (percentage agreement 97% and k = 0.939).

This assessment evaluated the quality of how the main findings of the study were summarized in the written report. In general, there was a remarkable lack of execution and/or description in the concealment, blinding, and intention-totreatment (ITT) analysis. The items for which the description

was lacking (very poor; <50%) in many studies were as follows (present ratio; %): ''Was the treatment allocation concealed?'' (45%); ''Was the patient blinded to the intervention?'' (40%); ''Was the care provider blinded to the intervention?'' (27%); ''Was the outcome assessor blinded to the intervention?'' (27%); and ''Did the analysis include an ITT analysis?'' (36%).

Meta-analysis

There were three RCTs on schizophrenia and two RCTs on depression. We could not perform a meta-analysis because of heterogeneity by difference of outcome measurement and intervention method (e.g., in dog, and in dog or cat).

Adverse events

Two studies reported no adverse events,^{13,19} and one study described three patients who were afraid of dogs and did not participate in the intervention.¹² There were no descriptions about adverse events in the other eight studies^{14–18,20–22} (Table 2).

Costs of intervention

Two studies^{13,16} described information about the cost of intervention (Table 2). Johnson et al. showed that dog visits were no more costly than human visits because all organizations provide dog visits on a volunteer basis.¹³ Allen et al. showed that the total calculated costs of initial canine training was \$10,000, lost investment income on initial training costs was 5% per annum compounded quarterly, animal maintenance was \$1000 per year, the expected canine service period was 8 years, and paid human assistance ranged from \$8 to \$12 per hour.

Discussion

This is the first SR of the cure effectiveness of ATT based on RCTs. Our study is unique because it summarized the evidence for each target disease according to ICD-10 classification. We assume that this study will be helpful to researchers who want to understand the effect of ATT comprehensively, and it could provide indispensable information for the organization that is going to make the guidelines according to each disease.

Among the 11 RCTs that were identified, target diseases and/or symptoms included schizophrenia, depression,

cancer, advanced heart failure, severe ambulatory disability, older adults admitted to skilled rehabilitation units, elderly persons with chronic psychiatric, medical, and neurologic conditions, and a mental illness diagnosis, as well as a history of alcohol/drug abuse or other addictive behaviors, and intervention methods included various approaches such as dog, dolphin, bird, cat, cow, rabbit, ferret, and guinea pig.

Tendency of target disease and outcome

The most commonly reported target diseases were "Mental and behavioral disorders (F10-20, 30-33, and unclear)",^{12,15,17-22} and the effect of AAT on these diseases was improved mental health (e.g., anxiety and mood), QoL, and social behavior. The main reason given in these articles for improved mental health was that the feeling and memory of an animal allowed the patient to be comfortable, pleasant, and happy. For example, Le Roux and Kemp²³ reported the following narrative comments by participants: "we talked to each other about the dog", "visits from the dog made me think about my own dog when I was young'', and 'at night I think about Pietie (the dog) and I smile'. In studies about the effects of AAT on anxiety, discomfort, fear, and pain, AAT has been variably applied as an accessory treatment for persons with addictions such as alcohol/drug abuses²² and as evasion of direct discomfort for undergoing medical treatment for cancer.13

The other reported target diseases were "Diseases of the circulatory system (I50.1)"¹⁴ and "Injury, positioning, and certain other consequences of external causes (T90-93)".¹⁶ The former evaluated hemodynamic parameters, cardiac index, and neurohormone levels as primary outcomes. The latter assessed psychological variables such as well-being, internal locus of control, and community integration. Improvements seen in these studies were mainly due to effects of buffering a person's reactivity to mental stressor^{24,25} and providing a sense of comfort and safety, and diverting attention away from the immediate stressors to a more pleasurable and calming interaction.²⁶

Validity of overall evidence based on quality assessment

Overall evidence and quality assessment

The Cochrane's list is the most important tool related to the internal validity of trials. In this SR, there were serious problems with the conduct and reporting of the target studies. Our review especially detected omissions of the following descriptions: method used to generate concealment, blinding, and ITT analysis. Descriptions of these items were lacking (very poor; <50%) in many studies.

In the Cochrane Review,²⁷ the eligibility criteria for a meta-analysis are strict, and for each article, heterogeneity and low quality of reporting must first be excluded. We could not perform a meta-analysis. Due to poor methodological and reporting quality and heterogeneity, there was insufficient evidence in the studies of AAT, and we are therefore unable to offer clearly any conclusions about the effects of AAT based on RCTs. Moreover, the CONSORT 2010²⁸ and the CONSORT for nonpharmacological trials checklists²⁹ are relatively new, but it was shown that the study protocol description and implementation for AAT studies should be subjected to these checklists.

Overall evidence

Most importantly, a specific adverse effect or harmful phenomenon such as allergy or fear for animals was not clearly observed overall, although we should consider the limitations and biases of these findings in the context of AAT patients/participants who are likely to enjoy animals. In other words, a person who dislikes animals will refuse intervention from the beginning.

The results of this study suggested that the RCTs conducted have been of relatively low quality. Only two RCTs were evaluated as ''good description (80–100%)''.^{15,22} AAT with dolphins is an effective treatment for mild to moderate depression, and is based on a holistic approach through interaction with animals in nature.¹⁵ AAT also plays an important role in enhancing the benefits of conventional therapy in psychiatric rehabilitation.²² Furthermore, AAT may have positive effects on schizophrenia and/or serious mental disorders. We assume that the direct effects of AAT are generally improvement of mental health, elimination of the sense of isolation, and an improvement in QoL.

Although further accumulation of RCT data is necessary, AAT may be effective treatment for the following diseases and symptoms: cancer and/or advanced life-limiting illnesses that affect mental state and QoL, impaired circulatory function with mechanical assistance, autistic spectrum disorders involving communicative skills, and self-reported outcomes for hospitalized patients and other patients with various clinical conditions.

Future research agenda to build evidence

Table 5 shows the future research agenda for studies of the cure effect by AAT. Researchers should use the appropriate checklists for research design and intervention methods, which would lead to improvement in the quality of the study, and would contribute to the accumulation of evidence. Researchers should also present not only efficacy data, but also a description of any adverse events or harmful phenomena and the reasons for withdrawals and non-participation. Many studies in this review did not describe these factors.

As a gradual increase of intervention is necessary in cure and rehabilitation programs, it is easy to assign settings like "Stage" for the intervention, such as first stage and second stage. Therefore, we also expect to understand the results and detailed descriptions of "pragmatic trials"³⁰ as well as "explanatory trials" for the treatment effect by AAT.

Bowen et al.³¹ suggested that public health is moving toward the goal of implementing evidence based intervention. But the feasibility of possible interventions, and whether comprehensive and multilevel evaluations are needed to justify them, must be determined. It is at least necessary to show the cost of such interventions. Introduction of an interventional method must be based on its cost—benefit, cost—effectiveness, and cost—utility.

Table 5Overall evidence and future research agenda to build evidence.						
Overall evidence in the present	Research agenda					
After having premised study environment limited to the people who liked animals very much, AAT may be an effective treatment for mental and behavioral disorders such as depression, schizophrenia, and alcohol/drug addictions, and is based on a holistic approach, through interaction with animals in nature.	 Satisfactory description and methodology including the CONSORT 2010 and the CONSORT for nonpharmacological trials Description of the reason of participants refused (non-participation) Description of adverse effects (e.g., allergy, infection, bit, and fear) and withdrawals Description of intervention dose (if pragmatic intervention) Description of cost Development of the original check-list for AAT 					

In addition, AAT as an intervention is unique and completely different than pharmacological or traditional rehabilitation methods. Therefore, it may be necessary to add some original items like herbal intervention,³² acupancture,³³ traditional Chinese medicine³⁴ and balneotherapy³⁵ to the CONSORT 2010 checklist as alternative and/or complementary medicines.

Strength and limitations

This review had several strengths: (1) the methods and implementation registered high on the PROSPERO database; (2) it was a comprehensive search strategy across multiple databases with no data restrictions; (3) there were high agreement levels for quality assessment of articles; and (4) it involved detailed data extraction to allow for collecting all articles' content into a recommended structured abstract. The conduct and reporting of this review also aligned with the PRISMA statement³⁶ for transparent reporting of SRs and meta-analyses.

This review had several limitations that should be acknowledged. Selection criteria were common across studies, as described above; however, bias remained due to differences in eligibility for participation in each study. Publication bias was a factor. Although there was no linguistic restriction in the eligibility criteria, we searched studies with only English and Japanese key words. In addition, this review reported on a relatively small and heterogeneous sample of studies. Moreover, we could not follow standard procedures for estimating the effects of moderating variables.

Conclusion

In a study environment limited to the people who like animals, AAT may be an effective treatment for mental and behavioral disorders such as depression, schizophrenia, and alcohol/drug addictions, and is based on a holistic approach through interaction with animals in nature.

To most effectively assess the potential benefits of AAT, it will be important for further research to utilize and describe (1) RCT methodology when appropriate, (2) the reasons for non-participation, (3) intervention dose, (4) adverse effects and withdrawals.

Contributors

TH, JK, SP, SO, HO, SH, HP, TO, and TA conceived the study and take responsibility for the summary of included studies and data extraction. KT and YM are the guarantors. HK and SO designed the study. HO, SP, TH and HK assessed the quality of articles. All authors critically described the manuscript for important intellectual content.

Funding

This study was supported by the Health and Labour Sciences Research Grants (Research on Health Security Control: ID No. H24-021; representative; Dr. Tsutani K) from the Japanese Ministry of Health, Labour and Welfare of Japan in 2012.

Conflict of interest statement

None declared.

Ethical approval

Not required.

Data sharing

No additional data available.

Acknowledgements

We would like to express our appreciation to Ms. Rie Higashino and Ms. Rinako Kai (paperwork), and Ms. Satoko Sayama (all searches of studies) for their assistance in this study.
